Test cases terminati con successo (trovati fault): M1-C1-AP1

Dato che per il primo incremento non era stato specificato un funzionamento ben preciso per il dispatcher, abbiamo deciso semplicemente di fargli attuare una scelta casuale tra i validator del sistema (purchè nessuno tra questi ultimi fosse coAuthor oppure mainAuthor della proposta).

Tuttavia il metodo che avevamo pensato per generare casualmente questi id, non funzionava correttamente.

Il seguente metodo cercava di individuare un Id casuale tra gli Id dei Validator disponibili nel sistema. Analizzando meglio questa failure ci siamo resi conto che questo metodo non poteva funzionare.

Abbiamo quindi deciso di sostituire questo metodo con uno maggiormente accurato. L'implementazione corrente utilizza una query per recuperare il Validator con il minimo numero di proposte assegnate.

Il metodo è stato quindi testato di nuovo, e il test adesso è fallito (non sono state trovate failure).

V2-P2	22/01/2024 -18:00	Passed

I seguenti test sono terminati con successo: V1-P1

Il metodo non riusciva a recuperare correttamente il validator.

All'interno dell'implementazione veniva chiusa la connessione prima di aver recuperato gli elementi dal result set.

E' stato quindi spostato semplicemente alla fine del metodo la chiusura della connessione.

Rilanciati i test case sono ora falliti(il sistema li ha quindi passati).

Integration Testing

Abbiamo effettuato test di integrazione per tutte quante le classi che possiedono una dipendenza con qualche altra classe.

ProposalDAO

La classe ProposalDAO utilizza le classi ValidatorDAO e AuthorDAO per poter funzionare. Andremo quindi ad effettuare di nuovo tutti quanti i test per i metodi che utilizzano questi oggetti, riutilizzando i test cases utilizzati nello unit testing ma utilizzando ValidatorDAO e AuthorDAO senza mockarli.
